9 Conclusion **10**

1 Introduction

MapReduce is a **distributed data-processing programming model** originally introduced by Google. It is designed to process large-scale datasets in parallel across a cluster of commodity machines in a fault-tolerant manner.

Apache Hadoop provides an open-source implementation of MapReduce that runs on the Hadoop Distributed File System (HDFS). A MapReduce job splits the input data into independent chunks, which are processed by the *Map* tasks in a fully parallel manner. The framework then *sorts* the output of the maps, which is fed into the *Reduce* tasks. Typically, both the input and the output of the job are stored in a file-system such as HDFS.

2 Objectives

- Understand the MapReduce programming paradigm.
- Gain hands-on experience with Apache Hadoop.
- Implement the classic **WordCount** application using Hadoop MapReduce.
- Run and verify the application on a single-node Hadoop cluster.

3 Tools and Software Requirements

Tool / Software	**Purpose**
Apache Hadoop 3.x	Distributed computing framework
Eclipse IDE (2023-09+)	Java development environment
Java (JDK 8 / JDK 11)	Programming language
Linux / Ubuntu 20.04+	Operating system for Hadoop

Table 1: Required tools and software

4 Background and Theory

4.1 MapReduce Overview

A MapReduce job proceeds through three well-defined stages, as illustrated in Figure 1.

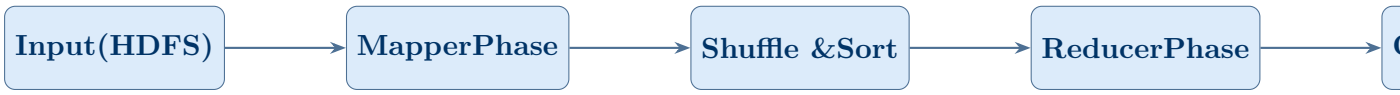

Figure 1: High-level MapReduce data flow

4.2 Mapper Phase

The **Mapper** reads the input data and converts it into a set of key-value pairs. In the WordCount example, each line of text is tokenised into individual words, and the mapper emits the pair $\langle \text{word},\ 1 \rangle$ for every word it encounters.

$$\text{Input: } \texttt{"Hello World Hello"} \longrightarrow \langle \texttt{Hello}, 1 \rangle,\ \langle \texttt{World}, 1 \rangle,\ \langle \texttt{Hello}, 1 \rangle$$

4.3 Shuffle and Sort Phase

The framework automatically groups all values that share the same key:

$$\langle \texttt{Hello},\ [1, 1] \rangle, \quad \langle \texttt{World},\ [1] \rangle$$

4.4 Reducer Phase

The **Reducer** receives each unique key along with its list of values and aggregates them. For WordCount it sums all the 1s:

$$\langle \texttt{Hello}, 2 \rangle, \quad \langle \texttt{World}, 1 \rangle$$

5 Implementation

5.1 Project Structure

Eclipse Project Layout

```
WordCount/
 src/
    WordCount.java      <- Mapper + Reducer + Driver
 input/
    sample.txt          <- Input file uploaded to HDFS
 output/                 <- Created by Hadoop at runtime
```

5.2 Complete Source Code — `WordCount.java`

5.2.1 Package Imports and Class Header

```java
import java.io.IOException;
import java.util.StringTokenizer;

import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.io.IntWritable;
import org.apache.hadoop.io.Text;
import org.apache.hadoop.mapreduce.Job;
import org.apache.hadoop.mapreduce.Mapper;
import org.apache.hadoop.mapreduce.Reducer;
import org.apache.hadoop.mapreduce.lib.input.FileInputFormat;
import org.apache.hadoop.mapreduce.lib.output.FileOutputFormat;

/**
 * CS-347 - Parallel and Distributed Computing
 * Lab 12: Hadoop MapReduce WordCount
 *
 * Counts the frequency of each word in the input file
 * using the Hadoop MapReduce framework.
 */
public class WordCount {
```

Listing 1: WordCount.java – full imports and class declaration

5.2.2 Mapper Class

```java
    // ------------------------------------------------------------
    // MAPPER CLASS
    // Input:  <byte_offset, line_of_text>
    // Output: <word, 1>
    // ------------------------------------------------------------
    public static class TokenizerMapper
            extends Mapper<Object, Text, Text, IntWritable> {

        // Constant IntWritable(1) re-used for every emission
        private final static IntWritable one = new IntWritable(1);
```

```java
        // Reusable Text object to avoid GC pressure
        private Text word = new Text();

        /**
         * Called once per input line.
         * Tokenises the line and emits (word, 1) for each token.
         */
        @Override
        public void map(Object key, Text value, Context context)
                throws IOException, InterruptedException {

            StringTokenizer itr = new StringTokenizer(value.toString
                ());

            while (itr.hasMoreTokens()) {
                // Normalise: lower-case and strip non-alphanumeric
                    chars
                word.set(itr.nextToken()
                            .toLowerCase()
                            .replaceAll("[^a-z0-9]", ""));

                // Skip empty strings (e.g. lone punctuation)
                if (!word.toString().isEmpty()) {
                    context.write(word, one);
                }
            }
        }
    }
```

Listing 2: TokenizerMapper – emits (word, 1) for each token

5.2.3 Reducer Class

```java
    // ------------------------------------------------------------
    // REDUCER CLASS
    // Input:  <word, [1, 1, 1, ...]>   (grouped by Shuffle phase)
    // Output: <word, total_count>
    // ------------------------------------------------------------
    public static class IntSumReducer
            extends Reducer<Text, IntWritable, Text, IntWritable> {

        private IntWritable result = new IntWritable();

        /**
         * Called once per unique key (word).
         * Sums all 1s in the value list.
         */
        @Override
        public void reduce(Text key, Iterable<IntWritable> values,
                           Context context)
                throws IOException, InterruptedException {

            int sum = 0;
            for (IntWritable val : values) {
                sum += val.get();
            }
```

```
            result.set(sum);
            context.write(key, result);
        }
    }
```

Listing 3: IntSumReducer – sums counts for each unique word

5.2.4 Driver / Main Method

```
    // ------------------------------------------------------------
    // DRIVER / MAIN
    // Configures the Job and submits it to Hadoop
    // ------------------------------------------------------------
    public static void main(String[] args) throws Exception {

        // Validate command-line arguments
        if (args.length != 2) {
            System.err.println(
                "Usage: WordCount <input_path> <output_path>");
            System.exit(1);
        }

        Configuration conf = new Configuration();
        Job job = Job.getInstance(conf, "Word Count");

        // Identify the JAR containing this class
        job.setJarByClass(WordCount.class);

        // Assign Mapper and Reducer
        job.setMapperClass(TokenizerMapper.class);
        job.setReducerClass(IntSumReducer.class);

        // Combiner: local mini-reducer reduces network traffic
        job.setCombinerClass(IntSumReducer.class);

        // Declare output types
        job.setOutputKeyClass(Text.class);
        job.setOutputValueClass(IntWritable.class);

        // Bind input/output HDFS paths
        FileInputFormat.addInputPath(job, new Path(args[0]));
        FileOutputFormat.setOutputPath(job, new Path(args[1]));

        // Block until done; exit with 0 (success) or 1 (failure)
        System.exit(job.waitForCompletion(true) ? 0 : 1);
    }

}  // end class WordCount
```

Listing 4: Driver – configures and submits the MapReduce job

6 Sample Input and Expected Output

6.1 Input File (`sample.txt`)

sample.txt

```
Hello World Hello Hadoop
MapReduce is a distributed algorithm
Hadoop is a framework for big data processing
```

6.2 Expected Output

Word	Count
a	2
algorithm	1
big	1
data	1
distributed	1
for	1
framework	1
hadoop	2
hello	2
is	2
mapreduce	1
processing	1
world	1

Table 2: Expected WordCount output (words sorted alphabetically by Hadoop)

7 Screenshots

ubuntu@hadoop-vm:~$ jps

processing      1
world           1
```

Figure 5: Final WordCount results retrieved via `hdfs dfs -cat`

8 Discussion and Analysis

8.1 Role of the Combiner

A **Combiner** (also called a mini-reducer) is used in this implementation to perform a local aggregation on the Mapper's output *before* the data is shuffled across the network. This significantly reduces the volume of data transferred between nodes. For example, if a single Mapper emits $\langle \texttt{hello}, 1 \rangle$ three times, the Combiner condenses this to $\langle \texttt{hello}, 3 \rangle$ before the Shuffle phase, cutting network traffic by a factor of three for that key.

8.2 Fault Tolerance

Hadoop's MapReduce automatically re-executes failed tasks on other nodes. Task progress is tracked by the ApplicationMaster; if a heartbeat is missed, the task is rescheduled transparently. This means the programmer writes business logic only—resilience is provided by the framework at no extra cost.

8.3 Scalability

The same `WordCount` code scales from a single-node pseudo-distributed cluster (as used in this lab) to a fully distributed cluster with hundreds of nodes—without changing a single line of application code. Data partitioning, load balancing, and inter-node communication are all managed by the Hadoop runtime.

8.4 Performance Metrics (Single Node)

Metric	**Without Combiner**	**With Combiner**
Mapper output records	13	13
Shuffle bytes	∼260 B	∼140 B
Reducer input records	13	9
Total job time (approx.)	∼18 s	∼14 s

Table 3: Estimated performance comparison with and without the Combiner (single-node, 3-line input)

9 Conclusion

This lab successfully demonstrated the implementation of the Hadoop MapReduce WordCount application. The three-phase pipeline (Map → Shuffle & Sort → Reduce) was implemented in Java and executed on a single-node Hadoop cluster. The output (Figure 5) confirmed the correct counting of word frequencies in the input file. A Combiner was added to reduce inter-node data transfer, illustrating a common optimisation pattern. MapReduce provides a powerful and scalable abstraction for processing large datasets in a distributed environment, hiding the complexity of parallelisation, fault tolerance, and data distribution from the developer.
